To study the changes in plasma endothelin (ET) in patients with acute myocardial infarction (AMI), 20 AMI patients, 26 patients with unstable angina pectoris (UAP) and 12 healthy subjects were enrolled into this study. The plasma ET levels were significantly higher in AMI group than in UAP group and healthy controls, and in UAP group than in healthy controls. The ET levels showed a significant positive correlation with the serum creatine phosphokinase (CPK) activities in AMI patients. The significantly higher ET levels in AMI patients suggested that ET might play an important role in the pathogenesis of AMI. Photoelectrochemical determination of Cu(II) in water using a silica-modified SnO(2) nanofiber array electrode. A photoelectrochemical (PEC) sensor for the determination of Cu(II) was developed using a silica-modified SnO(2) nanofiber array electrode. This electrode was prepared by hydrothermal synthesis in the presence of a silica precursor (TEOS) and a core-shell structure was formed via in-situ reaction between the inorganic silica and the SnO(2) surface. The silica-modified SnO(2) nanofiber array electrode was characterized by transmission electron microscopy (TEM) and cyclic voltammetry (CV). The Cu(II) reduction of the silica-modified SnO(2) nanofiber array electrode was studied and the effect of silica deposition was investigated. The PEC sensing system was designed and the sensor response to Cu(II) was evaluated. The results indicate that the silica-modified SnO(2) nanofiber array electrode has an enhanced electrochemical activity for the reduction of Cu(II) and a favorable affinity for the proton transfer from aqueous to the electrode, and its sensitivity is greatly improved. The enhanced electrochemical activity of the electrode is attributed to the Si-O-Sn interaction. 82157476af
